Abstract—This paper presents an approach to prediction based on a new interval type-2 intuitionistic fuzzy logic system (IT2IFLS) of Takagi-Sugeno-Kang (TSK) fuzzy inference. The gradient descent algorithm (GDA) is used to adapt the parameters of the IT2IFLS. The empirical comparison is made on the basis of a new interval type-2 intuitionistic fuzzy logic system (IT2IFS) of Takagi-Sugeno-Kang (TSK) fuzzy inference. The gradient descent algorithm (GDA) is used to adapt the parameters of the T1FLS (10), (11).

To the knowledge of the authors, there is currently no work in the literature where interval type-2 intuitionistic fuzzy set (IT2IFS) is applied in a fuzzy logic inference system. Our motivation is to apply IT2IFS to model uncertainty in data. In this study, an IT2IFS based on TSK fuzzy inference system (FIS) is presented and the learning algorithms for the adaptation of its parameters are derived.

The rest of the paper is structured as follows: In section II, IFS, T2IFS and IT2IFS are defined. In section III, IT2IFLS is designed and parameter update rules are derived. We present our results in Section IV, and conclude in section V.

I. INTRODUCTION

Fuzzy set (FS) theory was introduced by Zadeh [1] as a generalisation of the classical notion of a set and a proposition to accommodate fuzziness (degree of truth) as expressed in natural or human language [2], [3]. The attraction of FS lie in the resulting model’s capacity to represent non-linear input/output relationships using qualitative IF-THEN rules [3]. Despite the extensive use of type-1 FS (T1FS) and its connotation of uncertainty, previous works have established that T1 fuzzy logic models uncertainty to a certain degree in many applications and may not handle or minimise the effects of uncertainties inherent in some real world applications [4]. To address this problem, Zadeh [5] proposed an extension of his previous T1FS theory to include type-2 fuzzy set (T2FS) theory capable of handling uncertainties that T1 struggles with because membership grades of T2FS are themselves fuzzy.

Atanassov [6] extended the concept of Zadeh’s fuzzy sets to intuitionistic fuzzy sets (IFSs), which deal with uncertainty by considering both the degrees of membership and non-membership of an element to a fuzzy set A with some degree of hesitancy. According to Olej and Hajek [7], the representation of attributes by means of membership and non-membership functions provides a better way to express uncertainty. Castillo et al [8] lend credence to this when they opined that the presence of non-membership or hesitation index gives more possibility to represent imperfect knowledge and to adequately describe many real world problems. Atanassov and Gargov [9] extended the concept of IFS to interval valued intuitionistic fuzzy sets (IVIFS) which are characterised by membership and non-membership functions and defined in the interval [0,1]. The resulting T2 fuzzy logic systems (FLSs) whose degrees of membership are intervals are capable of providing better performance in some applications than the T1FLSs [10], [11].

When \( \nu_{A^*}(x) = 1 - \mu_{A^*}(x) \) for every \( x \in X \), then the set \( A \) is a fuzzy set. Moreover, Atanassov also specified an hesitation degree, \( \pi \), defined as 1 minus the sum of the degree of membership and non-membership of an element to a set. That is, \( \pi_{A^*}(x) = 1 - (\mu_{A^*}(x) + \nu_{A^*}(x)) \). This is called the hesitancy factor or intuitionistic fuzzy index of \( x \) in \( A^* \).

B. Type-2 Intuitionistic Fuzzy Set (T2IFS)

Here, we provide, for the first time, a new definition for a T2IFS. A T2FS \( A^* \) in the universe of discourse, \( X \) consists of type-2 membership and non-membership grades of \( x \in X \) defined as \( \mu_{A^*}(x, u) : u \in J_x^\mu \subseteq [0,1] \) and \( \nu_{A^*}(x, u) : u \in J_x^\nu \subseteq [0,1] \) respectively. The primary membership \( (J_x^\mu) \) and primary non-membership \( (J_x^\nu) \) of element \( x \in A^* \) are elements in the domain \( (x, u) \) which form supports of T2IFS in the third
Definition 3. A T2IFS denoted by \( \tilde{A}^* \) is characterised by a type-2 membership function \( \mu_{\tilde{A}^*}(x, u) \), and a type-2 non-membership function \( \nu_{\tilde{A}^*}(x, u) \), i.e.,
\[
\tilde{A}^* = \{(x, u), \mu_{\tilde{A}^*}(x, u), \nu_{\tilde{A}^*}(x, u) \mid \forall x \in X, \forall u \in J^\mu_x, \forall u \in J^\nu_x \}
\]
in which \( 0 \leq \mu_{\tilde{A}^*}(x, u) \leq 1 \) and \( 0 \leq \nu_{\tilde{A}^*}(x, u) \leq 1 \) where \( \forall u \in J^\mu_x \) and \( \forall u \in J^\nu_x \) conform to the T1 constraint that \( 0 \leq \mu_{\tilde{A}^*}(x) + \nu_{\tilde{A}^*}(x) \leq 1 \). That is, when uncertainties disappear, a T2 membership and non-membership functions must reduce to a T1 membership and non-membership functions respectively. Also the amplitudes of both membership and non-membership functions must lie in the closed interval of 0 and 1. That is, \( 0 \leq \mu_{\tilde{A}^*}(x, u) \leq 1 \) and \( 0 \leq \nu_{\tilde{A}^*}(x, u) \leq 1 \). Alternatively,
\[
\int_{x \in X} \left[ \int_{u \in J^\mu_x} \int_{u \in J^\nu_x} \left\{ \mu_{\tilde{A}^*}(x, u), \nu_{\tilde{A}^*}(x, u) \right\} / (x, u) \right]
\]
where \( \int \int \int \) represents union over all admissible values of \( x \) and \( u \) for the membership and non-membership over a continuous universe of discourse, and \( \int \) is replaced by \( \sum \) for discrete universe of discourse. When the secondary membership functions \( \mu_{\tilde{A}^*}(x, u) = 1 \), and secondary non-membership functions \( \nu_{\tilde{A}^*}(x, u) = 1 \), a T2IFS translates to an IT2IFS (see Figure 1 and Equation (1)).

III. INTERVAL TYPE-2 INTUITIONISTIC FUZZY LOGIC SYSTEM

Similar to a type-2 fuzzy logic system (T2FLS), a T2FLS consists of the fuzzifier, rule base, fuzzy inference engine and output processing module but because of the intuitionism involved in the fuzzy set, we shall refer to the T2FLS modules as intuitionistic fuzzifier, intuitionistic rule base, intuitionistic fuzzy inference engine and intuitionistic output processor.

A. Fuzzification

The fuzzification process involves the mapping of a numeric input vector \( x \in X \) into an IT2IFS \( \tilde{A}^* \) in \( X \) which activates the inference engine. In this study, intuitionistic Gaussian membership and non-membership functions with uncertain standard deviation are utilised which are defined as follows.

\[
\overline{\mu}_{ik}(x_i) = \exp \left( \frac{-(x_i - c_{ik})^2}{2\sigma^2_{ik}} \right) \ast (1 - \pi_{c,ik}(x_i))
\]
\[
\mu_{ik}(x_i) = \exp \left( \frac{-(x_i - c_{ik})^2}{2\sigma^2_{ik}} \right) \ast (1 - \pi_{c,ik}(x_i))
\]
In this study, model II is adopted to investigate the reasoning behind IT2IFLS with learning ability similar to adaptive-neural network-based fuzzy inference system (ANFIS) [15] and T2-ANFIS [16] approaches. In our study, the antecedent parts are IT2IFS while the consequent parts are crisp values. An IT2IFLS structure with two inputs, three membership functions and nine rules is as shown in Figure 2. According to [18], the output of IFIS-TSK can be computed using two approaches: (i) by the composition of membership output, $y^\mu$ and non-membership output functions $y^\nu$ (ii) by direct defuzzification. In this study, the former approach is adopted and the output of IT2IFLS is defined as follows:

$$y = \frac{(1 - \beta) \sum_{k=1}^{M} (f_k^\mu + f_k^\nu) y_k^\mu}{\sum_{k=1}^{M} f_k^\mu + \sum_{k=1}^{M} f_k^\nu} + \frac{\beta \sum_{k=1}^{M} (f_k^\mu + f_k^\nu) y_k^\nu}{\sum_{k=1}^{M} f_k^\mu + \sum_{k=1}^{M} f_k^\nu}$$

where $f_k^\mu$, $f_k^\nu$, $f_k^\nu'$ and $f_k^\nu''$ are the lower membership, upper membership, lower non-membership and upper non-membership firing strength respectively. In this study, the implication operator employed is the “prod” t-norm such that:

$$\begin{align*}
 f_k^\mu(x) &= \mu_{\tilde{A}^*_{1k}}(x_1) \ast \mu_{\tilde{A}^*_{2k}}(x_2) \ast \cdots \ast \mu_{\tilde{A}^*_{nk}}(x_n) \\
 f_k^\nu(x) &= \tilde{\mu}_{\tilde{A}^*_{1k}}(x_1) \ast \tilde{\mu}_{\tilde{A}^*_{2k}}(x_2) \ast \cdots \ast \tilde{\mu}_{\tilde{A}^*_{nk}}(x_n) \\
 f_k^\nu'(x) &= \mu_{\tilde{\mu}^*_{1k}}(x_1) \ast \mu_{\tilde{\mu}^*_{2k}}(x_2) \ast \cdots \ast \mu_{\tilde{\mu}^*_{nk}}(x_n) \\
 f_k^\nu''(x) &= \tilde{\mu}_{\tilde{\mu}^*_{1k}}(x_1) \ast \tilde{\mu}_{\tilde{\mu}^*_{2k}}(x_2) \ast \cdots \ast \tilde{\mu}_{\tilde{\mu}^*_{nk}}(x_n)
\end{align*}$$

where * is the “prod” operator, $y_k^\mu$ and $y_k^\nu$ are the output of the $k$th rule corresponding to membership and non-membership firing strength respectively. In IT2IFLS-TSK, the final output is a weighted average of each IF-THEN rule’s output and as such do not require any defuzzification procedure [19]. The parameter $\beta$ is a user defined parameter, $0 \leq \beta \leq 1$; specifying the contribution of the membership and non-membership values in the final output. Obviously, if $\beta = 0$, the outputs of the IT2IFLS is determined by the membership function and if $\beta = 1$, then only the non-membership will contribute to the system’s outputs. This study utilizes gradient descent algorithm (GDA) for the update of both the antecedent and the consequent parts of the rules. The cost function for a single output is defined as:

$$E = \frac{1}{2} (y^a - y)^2$$
where $y^*$ is the actual output and $y$ is the network output. The parameter update rules are as follows:

$$w_{ik}(t + 1) = w_{ik}(t) - \gamma \frac{\partial E}{\partial w_{ik}}$$ \hspace{1cm} (6)

$$b_k(t + 1) = b_k(t) - \gamma \frac{\partial E}{\partial b_k}$$ \hspace{1cm} (7)

$$c_{ik}(t + 1) = c_{ik}(t) - \gamma \frac{\partial E}{\partial c_{ik}}$$ \hspace{1cm} (8)

$$\sigma_{1,ik}(t + 1) = \sigma_{1,ik}(t) - \gamma \frac{\partial E}{\partial \sigma_{1,ik}}$$ \hspace{1cm} (9)

$$\sigma_{2,ik}(t + 1) = \sigma_{2,ik}(t) - \gamma \frac{\partial E}{\partial \sigma_{2,ik}}$$ \hspace{1cm} (10)

$$\pi_{c,ik}(t + 1) = \pi_{c,ik}(t) - \gamma \frac{\delta E}{\delta \pi_{c,ik}}$$ \hspace{1cm} (11)

$$\pi_{var,ik}(t + 1) = \pi_{var,ik}(t) - \gamma \frac{\delta E}{\delta \pi_{var,ik}}$$ \hspace{1cm} (12)

where $\gamma$ is the learning rate (step size) that must be carefully chosen as a large value may lead to instability, and small value on the other hand may lead to a slow learning process. The learning rate and IF-indexes for this study are fixed. Their adaptations will be considered in a future work. The derivatives in Equations (6) and (7) are computed as follows:

$$\frac{\partial E}{\partial w_{ik}} = \frac{\partial E}{\partial y} \frac{\partial y_{ik}}{\partial w_{ik}} = \sum_k \frac{\partial E}{\partial y} \left[ \frac{\partial y_{ik}}{\partial y} \frac{\partial y_{ik}}{\partial w_{ik}} + \frac{\partial y_{ik}}{\partial y} \right]$$

$$= (y(t) - y^*(t)) \ast \left[ (1 - \beta) \left( \frac{\sum_{k=1}^{M} f_k \mu_k}{\sum_{k=1}^{M} f_k + \sum_{k=1}^{M} T_k} \right) + \beta \left( \frac{\sum_{k=1}^{M} f_k \mu_k}{\sum_{k=1}^{M} f_k + \sum_{k=1}^{M} T_k} \right) \right] \ast x_i$$

$$\frac{\partial E}{\partial b_k} = \frac{\partial E}{\partial y} \frac{\partial y_{ik}}{\partial b_k} = \sum_k \frac{\partial E}{\partial y} \left[ \frac{\partial y_{ik}}{\partial y} \frac{\partial y_{ik}}{\partial b_k} + \frac{\partial y_{ik}}{\partial y} \right]$$

$$= (y(t) - y^*(t)) \ast \left[ (1 - \beta) \left( \frac{\sum_{k=1}^{M} f_k \mu_k}{\sum_{k=1}^{M} f_k + \sum_{k=1}^{M} T_k} \right) + \beta \left( \frac{\sum_{k=1}^{M} f_k \mu_k}{\sum_{k=1}^{M} f_k + \sum_{k=1}^{M} T_k} \right) \right] \ast 1$$

where $y_k$ is defined as in Equation (4). The derivatives in Equations (8) to (12) are computed as follows:

$$\frac{\partial E}{\partial c_{ik}} = \sum_k \frac{\partial E}{\partial y} \left[ \frac{\partial y_{ik}}{\partial y} \frac{\partial \mu_{ik}}{\partial c_{ik}} + \frac{\partial y_{ik}}{\partial y} \frac{\partial T_{ik}}{\partial c_{ik}} \right]$$

$$\frac{\partial E}{\partial \sigma_{1,ik}} = \sum_k \frac{\partial E}{\partial y} \left[ \frac{\partial y_{ik}}{\partial y} \frac{\partial \mu_{ik}}{\partial \sigma_{1,ik}} + \frac{\partial y_{ik}}{\partial y} \frac{\partial T_{ik}}{\partial \sigma_{1,ik}} \right]$$

where:

$$\frac{\partial y_{ik}}{\partial \mu_k} = \frac{\partial y_{ik}}{\partial \mu_k} \left[ \frac{\partial y_{ik}}{\partial \mu_k} \frac{\partial \mu_{ik}}{\partial \sigma_{1,ik}} + \frac{\partial y_{ik}}{\partial \mu_k} \right]$$

$$\frac{\partial y_{ik}}{\partial \sigma_{2,ik}} = \sum_k \frac{\partial E}{\partial y} \left[ \frac{\partial y_{ik}}{\partial y} \frac{\partial \mu_{ik}}{\partial \sigma_{2,ik}} + \frac{\partial y_{ik}}{\partial y} \frac{\partial T_{ik}}{\partial \sigma_{2,ik}} \right]$$

The derivatives:

$$\frac{\partial \mu_{ik}(x_i)}{\partial \sigma_{1,ik}} = (1 - \pi_{c,ik}) \ast (x_i - c_{ik}) \ast \exp \left( \frac{-(x_i - c_{ik})^2}{2 \ast \sigma_{1,ik}^2} \right) \ast \sigma_{1,ik}^2$$

$$\frac{\partial \pi_{ik}(x_i)}{\partial \sigma_{2,ik}} = (1 - \pi_{c,ik}) \ast (x_i - c_{ik}) \ast \exp \left( \frac{-(x_i - c_{ik})^2}{2 \ast \sigma_{2,ik}^2} \right) \ast \sigma_{2,ik}^2$$

are obtained in the same manner as Equations (13) to (16). With the use of a t-norm prod operator,

$$\frac{\partial f_k}{\partial \mu_{ik}} = \prod_{j=1,j\neq i}^{M} \mu_{jk}, \frac{\partial f_k}{\partial \pi_{ik}} = \prod_{j=1,j\neq i}^{M} \pi_{jk}$$

The parameter $\beta$ in Equation (5), initially set at 0.5, is learned to allow for adaptive adjustment of the membership and non-
membership in the final output. The value of $\beta$ is adjusted as follows:

$$\beta(t + 1) = \beta(t) - \gamma \frac{\partial E}{\partial \beta} = \frac{\partial E}{\partial \beta} = \frac{\partial E}{\partial y} \frac{\partial y}{\partial \beta}$$

$$= (y - y^\mu) \left( \sum_{k=1}^{M} \left( f_k^L + f_k^R \right) * y_k^L \right)$$

$$- \sum_{k=1}^{M} \left( f_k^L + \frac{\tau}{f_k^R} \right) * y_k^L$$

$$+ \sum_{k=1}^{M} \mu_k^L + \sum_{k=1}^{M} \frac{\tau}{f_k^R} \right)$$

Next, we present our experimental analysis and discussion of simulation results. The performance criterion used for all experiments is the root mean square error (RMSE) which is defined as:

$$RMSE = \sqrt{\frac{1}{N} \sum_{i=1}^{N} (y^\mu - y)^2}$$

where $y^\mu$ is the desired output and $y$ is the output of the model, $N$ is the number of testing data points.

IV. EXPERIMENTS AND RESULTS

A. Mackey Glass Prediction

Mackey-Glass is a well known time series dataset defined by the following differential delay equation:

$$\frac{dx(t)}{dt} = \frac{a * x(t - \tau)}{1 + x(t - \tau)^n} - b * x(t)$$

where $a$, $b$ and $n$ are constant real numbers, $t$ is the current time and $\tau$ is a non-negative time delay constant. The system tends to display a deterministic/periodic behaviour at $\tau \leq 17$ which turns chaotic when $\tau > 17$. For comparison with other works in the literature such as [14], [20]–[23], where the target output is chosen as $x(t + 6)$, from input vector $(x(t - 18), x(t - 12), x(t - 6), x(t))$ and $\tau = 17$. For each input in this study, two intuitionistic Gaussian membership functions with uncertain standard deviation are used. Similar to [22], the 1000 learning data are generated from time series $(t = 19-1018)$ with the first 500 data points used for training and the remaining 500 for testing. The results of applying different approaches to the prediction of Mackey-Glass are listed in Table I. As shown in Table I, IT2IFLS outperforms the modified differential evolution radial basis function neural network (MDE-RBF NN) and the fuzzy approaches.

For a fair comparison with IT2FLS(TSK) [14], another experiment is conducted with the same computational settings, and number of training (1000) and testing (200) datasets as reported in [14]. The parameters of IT2FLS(TSK) are updated using GDA and equally used the same parameter $\beta$ to adjust the upper and lower values of the membership grades in the final output. As shown in Table II, after training, IT2IFLS outperforms IT2FLS(TSK) with the RMSE of 0.0168. We also implemented a T1 intuitionistic fuzzy logic system (IFLS) for Mackey-Glass prediction in order to evaluate the performance of the IT2IFLS over its T1 model. From Tables I and II, IT2IFLS outperforms IFLS because of the extra degrees of freedom offered by the FOUs of the IT2IFLSs.

B. System Identification

For further evaluation, IT2IFLS is applied to a non-linear system identification problem where the dataset is generated by the following differential equation:

$$y(t + 1) = \frac{y(t)}{1 + y^3(t)} + u^3(t)$$

The variables $u(t)$ and $y(t)$ are used as inputs while $y(t + 1)$ is the desired output. Training samples are generated using $u(t) = sin(2\pi t/100)$. We adopt similar computational set up in [25]–[29] with 500 epochs and 200 samples. Similar to IT2IFLS, the parameters of T2FLS (Singleton and TSK)
are tuned using GDA. The results in Table III show that the IT2IFLS outperforms both forms of T2FLSs. Our approach is also compared with three evolving T2FLSs namely, self-evolving interval type-2 fuzzy neural network (SEIT2FNN) utilising IT2FS in the antecedents and TSK interval type-1 set in the consequent, TSK-type-based self-evolving compensatory IT2FNN (TSCIT2FNN) which utilises IT2FS in the antecedent and a crisp linear model in the consequent and evolving type-2 neural fuzzy inference system (eT2FIS) with antecedent T2FS and Mamdani-type consequent. As shown in Table III, IT2IFLS exhibits a low level of RMSE over these evolving T2FLSs. In particular, the performance of IT2IFLS is compared with Type-2 TSK Fuzzy Neural System (Type-2 TSK FNS) [28], TSCIT2FNN [26] and SIT2FNN [29], which also utilised the parameter $\beta$ to adjust the contribution of upper and lower membership values in their final outputs. The results show a clear performance improvement of IT2IFLS over Type-2 TSK FNS, TSCIT2FNN and SIT2FNN. We also constructed an IFLS in order to compare the performance of the IT2IFLS with its T1 model on system identification. From Table III, there is a significant performance improvement of IT2IFLS over IFLS on system identification.

V. CONCLUSION

In this study, an IT2IFLS-TSK approach to prediction is presented. The IT2IFLS can accommodate more imprecision thereby modelling imperfect and imprecise knowledge better than some IT2FLS. The key point in this design is in the IF-index which models the level of uncertainty of every element in each set. In future, we intend to learn the parameters of the IT2IFLS using Gaussian membership function with uncertain mean and also to train IT2IFLS using hybrid approach of GD and Kalman filter and to evaluate these on real world datasets. We also intend to apply IFS to general T2FLS.
